Foreword by Roland N. Horne	xix
Foreword by Bernard J. Duroc-Danner	xx
Chapter 1. Pressure Transient Analysis in Drawdown and Buildup	
Background to Transient Pressure Analysis	1
Introduction	1
Development of pressure testing	2
Exploration well testing	4
Radial Flow Theory	14
The basic flow equations	14
Fluid of constant compressibility	16
Further development of the accumulation term	17
Linearization of the radial flow equation	19
Initial and boundary conditions	20
Dimensionless form of the diffusivity equation	23
The line source analytical solution in an infinite reservoir	27
Wellbore damage and improvement effects	30
Analytical solution for the case of a bounded circular reservoir	32
Analytical solution for a constant pressure outer boundary	35
SPE field units	36
The depth of investigation and radius of drainage	37
The dynamics of reservoir pressure response	44
Pressure Drawdown Testing	46
Introduction	46
Pressure drawdown analysis in infinite-acting reservoirs	47
The Principle of Superposition	52
Introduction	52
Multiple-well situations	52
Variable rate situations	53
Pressure Build-up Testing	55
Introduction	55
Pressure buildup test analysis during the infinite-acting period	57
After production	61
Determination of reservoir parameters	63
Impulse test in a tight reservoir	68
Peaceman probe radius	68
Transient productivity index, J_t	70
Notes	72

Chapter 2. Wellbore Storage and Type Curve Matching

Wellbore Storage.	73
Introduction	73
Liquid-filled wellbore	75
Early time behavior of a well with storage	79
Practical use of the wellbore storage calculation	81
Solutions to the diffusivity equation in Laplace space.	82
The Stehfest algorithm	84
Well with storage and skin	85
Type Curve Matching	88
Introduction	88
Log-log type curve	88
Type curve based on t_D/C_D	91
Type Curve Matching using the Pressure Derivative.	96
Derivative analysis	98
Middle time region (MTR) derivative match	104
t_D/C_D type curve including the derivative	105
Finite wellbore radius solution.	107
Analysis of Buildup Responses—The Producing Time Effect.	111
Equivalent drawdown time.	111
Desuperposition.	117
Nonideal Wellbore Storage.	119
Introduction	119
Gas phase redistribution.	124
Empirical models of nonideal wellbore storage	130
Rising liquid level.	135
Downhole shut-in tools.	139
Falling liquid level in water injection wells	143
Numerical wellbore simulator	143
Well Cleanup and Changing Skin	145
Theory	145
Field examples.	147
Notes.	152

Chapter 3. Semi-Infinite System Late Transient Analysis

Introduction to Fault Detection.	153
Drawdown Analysis in the Case of a Single Linear Discontinuity.	154
Hemiradial flow	158
Build-up Analysis in the Case of a Single No-flow Boundary	160
Perturbed radial cylindrical buildup.	162
Radius of investigation in build-up testing	164
Reservoirs with Multiple No-flow Boundaries	167
Elementary Fault Systems.	168

Constant Rate Drawdown Theory for Semi-infinite Systems.	171
Analysis Methods for Constant Rate Drawdown (CRD) Tests.	175
t_D/L_D^2 derivative type curve.	176
Constant Rate Build-up (CRB) Theory for Semi-infinite Systems.	179
Optimum form of build-up derivative presentation	182
Field Examples.	184
North Sea example—Oseberg Field	184
Partially Communicating Faults (PCFs).	186
Introduction	186
Active well response	188
Linear composite system	191
Finite element method (FEM) numerical simulation of a PCF	193
Observation well response	193
Linear composite system	200
Homogeneous system	201
PCF in a channel reservoir	202
Pulse testing	206
Notes.	208

Chapter 4. Well in a Bounded Drainage Area

Reservoir Limit Testing	209
Introduction	209
Average reservoir pressure	210
Dietz semi-steady-state shape factors	212
Full analytical solution.	213
Semi-steady-state depletion and reservoir limit testing	214
Analysis of a reservoir limit test	217
Pressure Build-up Analysis in Bounded Systems	220
Introduction	220
Conditions for applicability of Horner analysis	225
Determination of the skin factor.	227
Matthews, Brons, and Hazebroek (MBH) method	228
Extended drawdown test with intermittent buildups	230
Reservoir monitoring	232
Concept of Synthetic Flowing Time	232
Single well in a closed compartment	232
Multiple well situations.	238
Synthetic test problem.	241
Developed Reservoir Effects —Slider's Method	244
Introduction	244
North Sea field example	249
Libyan field example	253
Determination of average pressure \bar{p}	254
Interference testing	255
Notes.	258

Chapter 5. Variable Rate Well Test Analysis

Introduction	259
Step Rate Flow Schedule	261
General superposition formula for step rate flow schedule	262
Infinite-acting Radial-cylindrical Flow	264
Drawdown theory	264
Drawdown superposition time function	265
Variable rate drawdown (VRD) semilog plot	265
Simplified variable rate analysis	269
Build-up theory	270
Evaluation of the skin factor S	271
Analysis of a Variable Surface Rate Buildup Using Drawdown Type Curve	272
Introduction	272
Synthetic afterflow deconvolution	274
Generalized Superposition Methods	276
Derivative diagnostic and type curve matching	284
Desuperposition and the Role of the Extrapolated Pressure	286
Time Transformation for Variable Properties	286
Superposition with a non-Darcy skin effect	289
Superposition Theory for Linear Flow	292
Linear flow (root of time) derivative	296
Variable Rate Extended Drawdown Testing	297
Bounded system behavior	297
Approximate deconvolution	300
Effect of build-up periods	306
Filtering for material balance studies	308
Pseudopressure and pseudotime transformation	309
Field example of an extended draw-down test	309
Further synthetic example	311
Permanent downhole gauges (PDGs)	313
Afterflow Measurement and Convolution	314
Introduction	314
Field example of afterflow convolution	316
Slug Testing, Closed Chamber Testing, and Pumping Well Buildups	320
Slug testing	320
Slug test analytical solution	329
Build-up analysis following variable rate drawdown	333
Integral method for the slug test flow period	334
Russian field example	340
Multiple slug test periods	345
Application to coal bed methane	348
Closed chamber test	349
Stress-dependent permeability	356
Notes	361

Chapter 6. Channel Sands and Parallel Faults

Introduction	363
Parallel Boundary Systems	367
Constant rate drawdown (CRD) in a semi-infinite system	367
Constant rate buildup (CRB)	373
Related systems	382
Offset well positions	386
Linear flow derivative	389
Bounded Rectangle	391
Constant rate drawdown	391
Synthetic example	395
Semi-steady-state depletion	400
Constant Rate Buildup in a Closed Rectangle	401
Build-up theory for rectangular systems	401
Desuperposition analysis	405
Use of the semi-infinite-acting time in build-up analysis	408
Matthews, Brons, and Hazebroek (MBH) method	409
Detection of a closed system	409
Amplified treatment of the extrapolated pressure	415
Depletion in a Channel System	418
Fluvial Systems	425
Sequence stratigraphy	425
Bilinear flow	434
Geostatistics	434
Constant-Pressure Boundary	437
Well Test Design	437
Notes	438

Chapter 7. Constant Pressure Boundaries

Constant-pressure Upper or Lower Boundary	439
Introduction	439
Theory	442
General derivative-type curve for a limited entry	449
Steady-state productivity	449
Depth of investigation with a constant-pressure boundary	452
Analysis of the drawdown behavior	454
The effect of wellbore storage	455
Miller–Dyes–Hutchison (MDH) Method	457
Determination of reservoir pressure	460
Infinite-acting radial flow	461
Field Examples	463
Single Vertical Constant-pressure Boundary	466
Non-intersecting vertical fracture	472
Notes	474

Chapter 8. Vertically Fractured Wells

Introduction	475
Uniform Flux and Infinite Conductivity Fractures.....	476
Introduction	476
Linear flow theory	477
Constant rate solution—uniform flux case	479
Constant rate solution—infinite conductivity case	481
Linear Flow Theory	483
Pseudoradial flow	488
Semi-steady-state (SSS) productivity index.....	489
Effect of wellbore storage	490
Type Curve Analysis	492
Effect of fracture face skin	494
Semilog analysis	495
Analysis of Build-up or Fall-off Tests	496
Specialized plots for buildup	496
Desuperposition.....	498
Generalized superposition plot.....	502
Automatic matching or nonlinear parameter estimation.....	503
Iranian field example of an acidized well.....	503
North Sea field example	506
Limited height fracture.....	507
Finite Conductivity Hydraulic Fractures	508
Finite conductivity fracture p_D function.....	510
Bilinear flow regime.....	513
Pseudolinear flow	519
Pseudoradial flow	522
Type curve matching	523
Permeability from prefracture test	524
Transient and SSS production.....	526
Layered systems	530
Bilinear Flow with Fracture Face Skin and Well-bore Storage.....	531
Pseudolinear flow	537
Nonintersecting (Distant) Fracture.....	542
Notes.....	548

Chapter 9. Dual Porosity Systems

Introduction	549
Models of Dual Porosity Systems.....	555
Radial diffusivity equation for the fracture system	555
Dimensionless groups	555
Material balance equation for the matrix system.....	557
Pseudo-semi-steady-state analysis	558
Dimensionless interporosity flow parameter	564

Warren and root PSSS dual porosity model	565
Transient interporosity flow model	566
Two-layer systems	570
General Solution to the Double Porosity Diffusivity Equation	573
Wellbore storage and skin.	576
Model Pressure Responses	577
Behavior of the PSSS dual porosity model.	577
Behavior of the transient dual porosity model	582
Effect of wellbore storage and skin	587
Analysis Methods	588
Constant rate drawdown—semilog plot	588
Constant rate buildup (CRB) analysis.	589
Well test analysis for dual porosity systems	592
Automatic matching	593
Fracture Network Theory	594
Iranian Field Examples	599
Well Q-18.	599
Well X-33T1	600
Radial Composite Behavior	601
Notes.	603

Chapter 10. Limited Entry and Double Permeability Systems

Well with Limited Entry or Partial Penetration	605
Introduction	605
Drawdown behavior of partially penetrating wells	606
Effects of Wellbore Storage.	610
Analysis of early time response using type curve matching.	612
Analytical solution.	613
Derivative type curve match	618
Determination of vertical permeability	618
Negative skin case	621
Spherical flow theory.	623
Double Permeability Model	628
Introduction	628
Limiting form of the dual permeability model	635
Aquifer support	637
Double permeability behavior	639
Analytical Solutions in Laplace Space.	640
Case II—Only One Layer Perforated	643
Case II—Fundamental (constant-rate) active layer response.	645
Well test interpretation.	648
Murchison field.	655

Vertical Interference Testing	655
Observation layer response	656
Effect of wellbore storage	662
Vertical Interference Testing Field Data	664
C_{DL} Type Curve	666
Simulation of vertical interference tests	667
Field examples	669
Conclusions	672
Shale Lens Model	672
Notes	676

Chapter 11. Radial Composite Systems

Radial Composite Systems	677
Introduction	677
Fundamental response	681
Derivative type curves	688
Build-up behavior	692
Aquifer influx	694
Gas block and liquid condensate dropout	702
Unfavorable displacement situations	706
Negative skin situation	706
Geological setting for the radial composite model	707
Formation damage as a radial composite	713
Radial Composite with a Closed Outer Boundary	715
Thermally Induced Fracturing (TIF)	716
Introduction	716
Rock mechanics of thermal fracturing	719
Simplified model of equilibrium fracture half length	724
Interpretation of pressure injection and fall-off tests	727
Step-rate test (SRT)	729
Fall-off Tests in Water Injection Wells—Effect of Saturation Profile	730
Displacement theory	730
Determination of mobility profiles	733
Determination of flood front radius, r_{ff}	735
Average pressure of inner region	735
Fall-off Tests in Gas Injection Wells	739
Notes	739

Chapter 12. Horizontal Wells

Introduction	741
Flow Regimes	745
Vertical radial flow	748
Effect of anisotropy	751

Anisotropic parallel boundary solution	753
Fractured well solution	759
Horizontal pseudo-radial flow	761
General Solution for a Horizontal Well	763
Derivative type curve	766
Acidized horizontal wells	776
Strip source solution	779
Evaluation of the Green's function solution	787
Pseudo-radial flow regime skin factor	788
Vertical lateral boundaries	790
Analysis Methods Based on Specialist Plots	795
Early time analysis—infinite-acting radial flow	795
Derivative analysis	797
Hemiradial vertical flow	798
Intermediate time analysis—linear flow regime	800
Late time analysis—horizontal pseudo-radial flow	803
Build-up analysis	804
Transient Deliverability	805
Constant-pressure Boundary	807
Layered Commingled Systems	814
Theory of a near-horizontal well penetrating several layers	814
Synthetic example	819
Horizontal multilateral wells	825
Effect of Lateral Boundaries	827
Closed systems	827
Dietz shape factors (C_A)	829
Highly Deviated (Slant) Wells	829
Hydraulically Fractured Horizontal Wells	832
Sinusoidal Wells	840
Radial Composite Behavior	841
Notes	842
 Chapter 13. Gas Well Testing	
Theory of Gas Well Testing	843
Introduction	843
Linearization of the radial flow equation for a real gas	844
Constant-rate inner boundary condition	847
Detection of depletion	851
Analysis Methods	854
Constant Rate Drawdown (CRD) analysis	854
Gas well field units	857
Constant rate buildup (CRB) analysis	858
Real gas pseudo-time t_a	862

Wellbore Storage in Gas Wells	865
Application of Agarwal pseudo-time transformation	865
Very low permeability reservoirs	874
Determination of rate-dependent skin coefficient D	876
Gas Reservoir Limit Testing	877
Behavior of a closed gas reservoir	877
Pseudo-time based on average pressure	877
Reservoir limit test	883
Variable (step) rate case	886
Semi-steady-state gas well deliverability	888
Simulated extended drawdown	890
Analytic simulation option	891
Step-rate Transient (SRT) Test	891
Methodology and test objectives	891
Variable rate drawdown (VRD) plot for gas wells	900
Prediction of the SSS deliverability of development wells	901
North Sea gas well test field example	902
Design of Step-rate Tests	906
Isochronal Testing and its Limitations	910
Reserves Proven by a Gas Well Test	917
Notes	917

Chapter 14. Automatic Model Matching

Introduction	919
Structure of fundamental (CSFR) p_D functions or models	919
Interpretation methodology	923
Storage and interrogation of tabulated dimensionless responses	930
Real-time Convolution	932
Introduction	932
Ideal wellbore storage and skin	932
Nonideal wellbore storage	940
Time-dependent skin and wellbore storage coefficient	941
Application to gas wells	941
Automatic Matching	944
Nonlinear regression	944
Model selection	955
Selection of data points	955
Advantages and disadvantages of nonlinear regression	956
Production Analysis: Prediction of Production Decline	957
Transient deliverability	957
Fractured well example	961
Fetkovich approximation	964
Semi-steady-state depletion	966
Closed system p_D functions	973
Notes	973

Chapter 15. Two Cell Compartmentalized Systems

Extended Drawdown Behavior.	975
Period of negligible support.	979
Time to reach total system semi-steady-state.	981
Dimensionless form of the material balance support	983
Superposition of material balance effect in a closed system	984
Late time drawdown derivative type curve	986
Analysis methods on the Cartesian graph.	990
Extended Build-up Behavior.	991
Derivative diagnostic.	993
Exponential approach region	995
Analysis of transient and semi-infinite-acting period	997
Build-up analysis by desuperposition.	998
Build-up derivative type curve.	1000
Synthetic Example	1006
Total System Productivity Index	1012
Effect of a Poor Cement Bond	1015
Reservoir Engineering Aspects of Compartmentalization.	1016
Field Examples.	1017
Further Field Examples	1018
Katnook field.	1018
Middle East carbonate.	1021
Notes.	1022

The following chapters are on the accompanying CD-ROM.

Chapter 16. Well Test Design

Introduction	1023
Background to test design	1023
Permeability estimate	1025
Review of seismic data.	1026
Decision to Test or Not	1026
Objectives of the Test.	1028
General objectives	1028
Skin cleanup	1032
Enhanced objectives	1033
Obtaining a permeability estimate	1034
Completion design.	1036
Forecasting of development well deliverability.	1037
Estimation of accessible hydrocarbon	1038
Tubing diameter selection	1040
Design Criteria	1041
Based on the depth of investigation	1041

Based on the duration of the wellbore storage effect.	1042
Wireline shut-in tools (SITs)	1044
Based on the removal of tidal effects	1044
Low-permeability systems	1045
Incorporation of production logging	1046
Role of Simulation in Test Design	1047
Application of a nodal analysis package.	1047
Role of analytical well test simulation	1052
Gauge selection and location	1053
Permanent downhole gauges	1054
Special Considerations for Gas Wells	1054
Classification of gas reservoirs.	1054
Step-rate test design.	1055
Design calculations related to wellbore storage	1057
Role of analytical simulation	1059
Rate control	1059
Problem of well cleanup	1060
Turner critical velocity	1063
Example gas well test design	1063
Estimation of reserves	1069
First gas well field example	1069
Second gas well field example	1071
Fractured wells	1071
Limitation on test rate due to environmental considerations	1072
Wellhead temperature constraints	1073
Compositional simulation	1073
Extremely high permeability	1073
Testing of the completion	1074
Testing of gas condensate wells	1074
Modern DST Testing Systems	1074
Separator selection.	1074
Multiphase flow measurement	1076
Fluid disposal	1078
Notes.	1078
Chapter 17. Multiphase Flow	
Introduction	1079
Linearization of the Continuity Equation	1084
Steady-state two-phase pseudopressure	1084
Radius of drainage	1086
Pseudopressure integrals	1088
Diffusivity Equation in Terms Of Two-Phase Pseudopressure	1091
Two-phase compressibility and pseudotime	1092
Two-phase material balance.	1095
Analytical Solutions to the Linearized System	1096
Case where the reservoir pressure is above the dew point.	1096

Analytical solutions in terms of two-phase pseudopressure	1101
Comparison with numerical simulation results	1102
Gas condensate well test methodology	1105
Reservoir pressure below the dew point	1107
Generation with a Pressure-dependent Viscosity Compressibility Product	1110
Sampling in Gas Condensate Systems	1111
Theory of Perrine and Martin	1114
Steady-state pseudopressure for solution gas drive	1116
Transient flow in solution gas drive	1117
Semi-steady-state depletion	1118
Build-up analysis in solution gas drive	1119
Case Studies	1120
Arun field	1120
Cupiagua field	1126
North Rankine field	1129
Britannia field	1129
Non-Darcy Flow in Gas Condensate Well Tests	1133
Raghavan et al. Field Examples	1138
Numerical Simulation of Gas Condensate Well Tests	1144
Barrios and Osorio studies	1144
Role of compositional modeling	1157
Notes	1158
 Chapter 18. Numerical Well Testing	
Numerical Techniques	1161
Introduction	1161
The finite element method	1167
Interaction of Geological Modeling and Well Test Interpretation	1167
Introduction	1167
Heriot-Watt fluvial reservoir project	1176
Geoskin concept	1184
Geological Object Framework	1185
Introduction	1185
Captain horizontal well	1191
Dual permeability with a horizontal well	1193
Nonintersecting fracture situations	1194
Shale lens problem	1198
Stacked channels	1201
Makassar Strait deepwater fields	1205
EPS derivative fingerprint library	1209
Multiple fault example	1209
Compartmentalized field example	1212
Conditional Simulation	1213

Interference Testing	1214
Introduction	1214
Dual permeability situations	1215
Vertical sealing faults with windows	1218
Conclusions	1221
Notes	1222
 Chapter 19. Layered Well Testing	
Introduction	1223
Direct measurement of layer pressures	1227
Well testing objectives	1229
Integration of well test interpretation and core analysis	1233
Commingled systems with horizontal wells	1234
Multilayer Convolution Algorithm	1234
Prediction of layer flow rates for a specified wellbore pressure history	1240
Two-Layer Situations	1242
Transient crossflow during buildup	1245
Early shut-in time rate transient	1245
Two-layer case studies	1247
Unequal initial pressure	1250
Incremental layer workover case	1252
Transient step-rate test (TSRT)	1252
Partially Bounded System	1253
Constant total rate drawdown	1253
Regime 1: Both layers infinite-acting	1257
Regime 2: Depletion of the bounded layer 1	1257
Regime 4: Layer 2 producing alone	1258
Draw-down type curve	1259
Buildup	1260
Derivative diagnostics	1263
Three-layer Synthetic Problem	1264
Dual Profile Build-up Test (DPBT)	1270
Basic form of DPBT	1270
Reservoir monitoring and automatic matching	1275
DPBT with NGWFT dual packer complement	1278
Transient Step-Rate Test	1279
Communicating Layers	1284
Introduction	1284
Pseudo-semi-steady-state (PSSS) crossflow model	1287
Embedded lens of high permeability—Geoskin	1294
Finite element numerical modelling	1306
Crossflow index	1307
Braided fluvial systems	1309
Development of crossflow modelling using partial productivity indices	1312
Design and simulation of workover treatments	1316

Synergistic Interpretation of Layered Well Tests	1319
Integration of core analysis data	1319
Effective flowing interval	1321
Upscaling core and log permeability data	1326
Natural fracturing	1330
Hydraulic Flow Units (HFUs).....	1331
Introduction	1331
Fundamental theory.....	1332
Hydraulic unit zonation process	1337
Field examples from clastic reservoirs	1340
Permeability prediction from core and log data	1343
Siberian field example	1349
Alternative lumped parameter approach.....	1352
Distributed Pressure Surveys	1354
Notes.....	1354

Chapter 20. Deconvolution in PTA

Introduction	1357
Convolution of a Variable Rate Response	1359
Iseger Algorithm.....	1361
Numerical Laplace Transformation	1369
Step Rate Schedules	1375
Deconvolution of a Variable Rate Response	1378
Application of Deconvolution	1382
Determination of reservoir volume	1382
Further Simulated Test Problems	1401
Gas well testing.....	1409
Application to Wireline Formation Testing.....	1410
Mini-DST.....	1410
Depth of Investigation.....	1415
Real-time Deconvolution	1418
Permanent Downhole Gauge (PDG) Data.....	1424
Build-up Analysis	1441
Partial Datasets	1444
Synthetic deconvolution	1471
Two-Cell Compartmentalized Systems	1472
Gas Well Testing.....	1476
Shell field example	1476
Notes.....	1483

Index.....	I-1

Foreword

by Roland N. Horne

Well test analysis is one of the cornerstones of reservoir analysis, as it is only through the wells that we ever have the opportunity to make direct contact with the reservoir. Nonetheless, the reservoir parameters of importance to us are not measurable directly, hence the need to make an indirect interpretation of pressure and flow rate transients in the process we call well test analysis. The need to solve the inverse problems inherent in well test analysis makes the field one of the most intricate mathematically, while still dependent intimately on the practical characteristics and accuracy of the pressure measurements themselves.

There are few in our field who accomplish the bridge between mathematical analysis and engineering practicality as proficiently as George Stewart. He has worked centrally in the field of well testing and well test analysis for much of his professional career, starting in the 1970s when he was one of the founding faculty members at the very successful Department of Petroleum Engineering at Heriot Watt University in Scotland. In addition to advising decades of student research projects in well test analysis, George has been a key figure in the development of well testing in an industrial context. He was the principal architect of one of the earliest and most successful commercial well test analysis software packages, as well as a leading participant in the development of the wireline formation tester class of downhole tools. Additionally, by extensive active involvement in real reservoir development projects, George has accumulated a vast personal encyclopedia of practical reservoir experience, which he is able to recall in great detail. Whatever proposition may be discussed in a professional meeting, George has an example that supports (or refutes) it.

In addition to being one of giants in the field, George Stewart's personality is memorable for his generosity of spirit. Here is a man who likes to do the job right, and to help others to do the job right as well. Known throughout the industry for his good nature and generous advice, George has shared his expertise and experience with many. This book is another manifestation of his sharing.

Roland N. Horne

Foreword

by Bernard J. Duroc-Danner

We view technology in the oilfield as a critical, even existential, competency at Weatherford. The convergence of accelerating decline rates, maturing reservoirs, and more complex well architecture drives this belief, and also has underpinned Weatherford's strategy for many years in our evergreen commitment to research and development.

My esteemed colleague George Stewart came to Weatherford through an acquisition in 2004 (Edinburgh Petroleum Services), which was part of this continued technology investment. With him came a plethora of both knowledge and experience in all elements of pressure transient analysis, or the science used to better understand the reservoir in conventional well testing and wireline formation evaluation.

At Weatherford, we have experienced firsthand how George's unique fusion of academic research, industrial experience, and instructional expertise has created practical, yet highly valuable, testing techniques in the various elements of our business. These include developing a new method for determining reservoir description for underbalanced drilling, as well as accelerating progress on our wireline formation testing efforts and coalbed methane well testing.

The pressure transient analysis reference series are just another example of George's unique blend of theory and practicality: the books and companion CD-ROMS provide a full exposition of the theory behind pressure transient analysis, but also offer numerous practical aspects illustrated by field examples. They also highlight George's main strength—he is not simply content to solve difficult problems. He works to ensure that he can teach others to solve them as well in ways that are easy to understand and replicate.

Sharing knowledge and best practices is essential to our industry's continued growth and health. We trust you will find the information contained in these series to be informative, accessible and useful in the much-needed ongoing requirement for better reservoir understanding.

Dr. Bernard J. Duroc-Danner
Chairman, President and CEO
Weatherford International Ltd.

Pressure Transient Analysis in Drawdown and Buildup

Background to Transient Pressure Analysis

Introduction

One of the greatest problems facing the petroleum engineer is that of characterizing the physical nature of the subterranean reservoir from which the crude oil or gas is produced. The significance which can be put on the results of sophisticated numerical simulations of reservoir performance is entirely dependent on the quality of reservoir description inherent in the model. The difficulty in obtaining a reliable description stems from the large scale and heterogeneous nature of the reservoir and the very limited number of points, i.e., wells, at which observations can be made. In the case of an offshore reservoir, this difficulty is compounded by the fact that the well spacing is much larger than that typical of onshore operation. There are several ways by which it is possible to gain information about the reservoir characteristics; the most important are given below:

- a) Seismic and associated geological studies
- b) Information obtained during the well drilling programme; this comprises the following:
 - 1) The analysis of cuttings and cores
 - 2) The interpretation of various logs
- c) Wireline formation testing
 - 1) Virgin reservoir (exploration and appraisal wells)
 - 2) Produced reservoir (new development wells)
- d) Transient pressure testing of wells (including production logging)
- e) Analysis of reservoir performance, e.g., through history matching a simulator

A consistent description of the reservoir can only be generated by collating and assessing all the available information from these different sources and synthesizing a coherent physical model of the system which minimizes inconsistencies in the data. Note that, in the reservoir

which can be expanded as follows:

$$\frac{\partial(\phi\rho)}{\partial t} = \phi \frac{\partial\rho}{\partial t} + \rho \frac{\partial\phi}{\partial t} = \phi c_l \rho \frac{\partial p}{\partial t} + \rho \frac{\partial\phi}{\partial p} \cdot \frac{\partial p}{\partial t} \quad (1-12)$$

where the liquid compressibility has been denoted c_l . On defining the compressibility of the formation as

$$c_f = \frac{1}{V_p} \frac{\partial V_p}{\partial p} \quad (1-13)$$

this may be written as

$$\frac{\partial(\phi\rho)}{\partial t} = \phi\rho(c_l + c_f) \frac{\partial p}{\partial t} \quad (1-14)$$

Although in reality the ϕ on the right-hand side of Eq. (1-14) is still a function of pressure, as a first approximation it can be treated as a constant, evaluated at some representative average formation pressure. In this form Eq. (1-14) adequately allows for the small effect of rock compressibility in all but the most exceptional circumstances.

A further refinement of Eq. (1-14) is warranted; in an undersaturated reservoir two liquids are in fact present—oil and immobile connate water—both of which are compressible. Hence the liquid compressibility c_l is given by the sum of two contributions:

$$c_l = S_{wc}c_w + S_o c_o \quad (1-15)$$

where c_w and c_o are the compressibilities of water and oil, and S_{wc} and S_o are the respective saturations. Thus, the compressibility c in the basic Eq. (1-11) is identified with the total system compressibility c_t , which is defined as

$$c_t = c_l + c_f = S_{wc}c_w + S_o c_o + c_f \quad (1-16)$$

Note that the permeability k in Eq. (1-11) is not the absolute permeability of the porous medium but the permeability to oil at the connate water saturation, i.e.,

$$k = k_o(S_{wc}) \quad (\text{the end-point permeability}).$$

Since the flow model assumes horizontal flow the permeability also refers to this direction, i.e., it is the radial permeability. When the total compressibility c_t is employed, the density ρ refers to the mass per unit pore volume of oil and connate water.

Analytical solution for the case of a bounded circular reservoir

Of course, no real reservoir is infinite in extent and the solution of the preceding section is only valid while the pressure transient is confined within the limits of a particular cylindrical volume. As soon as the pressure at the outer boundary starts to deviate from the initial value, one of the external boundary conditions becomes operative. Usually, the alternative form most consistent with physical reality is the no flow constraint (1-29). Occasionally, the mathematical boundary may coincide with a physical barrier, i.e., the extremity of the reservoir. However, a much more common situation arises when several producing wells, placed more or less symmetrically, are distributed over the reservoir. In this case no flow boundaries arise because of the reservoir drainage patterns which develop; deviation from the transient, infinite reservoir solution occurs when the expanding, radially symmetric pressure disturbances from adjacent wells first come in contact. The concept of drainage volumes will be taken up in detail later.

In the meantime, an individual well will be assumed to be located in the centre of a cylindrically shaped drainage area of uniform thickness h and external radius r_e with no flow across the external boundary. The dimensionless differential system now takes the form

$$\frac{\partial p_D}{\partial t_D} = \frac{1}{r_D} \frac{\partial}{\partial r_D} \left(r_D \frac{\partial p_D}{\partial r_D} \right) \quad 1 \geq r_D \geq r_{De} \quad (1-66)$$

$$t_D < 0, \quad p_D = 0 \quad \text{all } r_D$$

$$r_D = 1, \quad \frac{\partial p_D}{\partial r_D} = -1 \quad \text{all } t_D > 0$$

and the corresponding equation in actual variables and parameters becomes for SSS flow

$$p_{wf}(t) = p_i - \frac{q_s B \mu}{2\pi k h} \left[\frac{2kt}{\phi \mu c_t r_e^2 2e} + \ln \frac{r_e}{r_w} - \frac{3}{4} + S \right] \quad (1-98)$$

where

$$p_{wfd} = p_D(1-t_D) = \frac{p_i - p_{wf}}{\frac{q_s B \mu}{2\pi k h}}$$

The pressure distribution in the reservoir during the SSS period is illustrated in figure 1–22 where the stabilized shape of the pressure profiles at successive times is apparent.

Fig. 1–22. Stabilized pressure distribution in SSS

Pressure Drawdown Testing

Introduction

The analytical solution to the diffusivity equation for a uniform pressure initial condition and a constant flow-rate inner boundary condition has led to an expression for the dynamic wellbore pressure behavior of a model reservoir having homogeneous formation permeability and instantaneous skin effect. The objective of a well test is to measure the dynamic response of an actual reservoir under these same conditions and determine unknown reservoir parameters by inference. The two most important such parameters are the permeability thickness product kh and the skin factor S . The productivity of a well can only be predicted if these quantities are known. The problem of well testing is essentially one of parameter estimation in which the unknown

One advantage of a modern electronic pressure transducer, with a high sampling rate, is that the last flowing pressure, $p_{wf}(\Delta t = 0)$, can be accurately determined as illustrated in figure 1–35; this is important for the calculation of the skin. Note that the clock time corresponding to $\Delta t = 0$ (the point at which the valve actually closes) can also be accurately bracketed. Precise estimates of pressure and time at $\Delta t = 0$ are necessary for the log–log diagnostic plots discussed in the next chapter. The analysis of a buildup by the CRB method can be carried out even when the rate is varying during the drawdown period as shown in figure 1–35. The equivalent constant rate drawdown time is defined as

$$t_p = \frac{Q}{q} \quad (1-149)$$

Here, Q is the cumulative volume produced over the whole flow period and q is the last, stabilized rate. This approach should not be used when there is a strongly declining rate in the flowing period, as in a slug (rising liquid level) test; in this case full superposition is necessary as described in chapter 5.

Fig. 1–35. Test precautions

In figure 1–36, a typical chart from the original Amerada gauge is depicted and it can be seen that during the flowing periods the bottom-hole pressure is actually increasing. This is the rising liquid level phenomenon apparent in many old DSTs and Horner analysis of the final buildup is not really recommended because of the implied rate variation. In 1976, the Hewlett-Packard company introduced the first quartz crystal pressure transducer and this proved essential for the satisfactory conduct of well tests in the high permeability North Sea basin. In figure 1–37, a Horner plot of a pressure buildup in a Piper (Occidental) well is shown where the total pressure change in the buildup (Δp_{BU}) is less than 5 psi; it is immediately apparent why a high-resolution pressure gauge is necessary in this application.

Fig. 2-10. Effective wellbore radius

The quantity $C_D e^{2S}$ is simply a dimensionless wellbore storage coefficient based on the effective wellbore radius: thus,

$$C_D e^{2S} = \frac{C_S}{2\pi\phi h c_t r_w^2} \cdot \frac{r_w^2}{r_{eff}^2} = \frac{C_S}{2\pi\phi h c_t r_{eff}^2} \quad (2-44)$$

Gringarten showed that the $p_D(C_D, S, t_D)$ information generated from the model represented by Eq. (2-29) could be presented as a family of curves of p_D versus t_D/C_D , each one characterized by a value of the parameter $C_D e^{2S}$.

The improved log-log type curve is shown on figure 2-11; it contains exactly the same information as the p_D versus t_D type curve only presented in a different manner. This $p_D - t_D/C_D$ type curve is used in the same manner as described previously. The test data are plotted as Δp versus t on a log-log graph of the same size as the type curve, i.e., compatible scales as indicated in figure 2-12a. This is then overlain and moved orthogonally, i.e., axes of both plots exactly parallel, until the best match is obtained as shown in figure 2-12b. A match point is then chosen as in figure 2-12c giving the following correspondences:

Pressure match:
$$[p_D]_M = \frac{2\pi k h [\Delta p]_M}{q\mu}$$

i.e.,
$$kh = \frac{q\mu [p_D]_M}{2\pi [\Delta p]_M} \quad (2-45)$$
